Abstract

This is the text of the abstract.

If P's answer is 'Bad!', Q will suddenly stop. But otherwise, Q will go back to the top, and start off again, looping endlessly back, till the universe dies and turns frozen and black.

Excerpt from Scooping the Loop Snooper (Pullum 2000))

1. Introduction

Löb's thereom has a variety of applications, from proving incompleteness of a logical theory as a trivial corrolary, to acting as a no-go theorem for a large class of self-interpreters (TODO: mention F_{omega}?), from allowing robust cooperation in the Prisoner's Dilemma with Source Code (), to curing social anxiety ().

"What is Löb's theorem, this versatile tool with wonderous applications?" you may ask.

Consider the sentence "if this sentence is true, then you, dear reader, are the most awesome person in the world." Suppose that this sentence is true. Then you, dear reader are the most awesome person in the world. Since this is exactly what the sentence asserts, the sentence is true, and you, dear reader, are the most awesome person in the world. For those more comfortable with symbolic logic, we can let X be the statement "you, dear reader, are the most awesome person in the world", and we can let A be the statement "if this sentence is true, then A." Since we have that A and $A \rightarrow B$ are the same, if we assume A, we are also assuming $A \rightarrow B$, and

hence we have B, and since assuming A yields B, we have that $A \to B$. What went wrong?¹

It can be made quite clear that something is wrong; the more common form of this sentence is used to prove the existence of Santa Claus to logical children: considering the sentence "if this sentence is true, then Santa Claus exists", we can prove that Santa Claus exists. By the same logic, though, we can prove that Santa Claus does not exist by considering the sentence "if this sentence is true, then Santa Claus does not exist." Whether you consider it absurd that Santa Claus exist, or absurd that Santa Claus not exist, surely you will consider it absurd that Santa Claus both exist and not exist. This is known as Curry's paradox.

Have you figured out what went wrong?

The sentence that we have been considering is not a valid mathematical sentence. Ask yourself what makes it invalid, while we consider a similar sentence that is actually valid.

Now consider the sentence "if this sentence is provable, then you, dear reader, are the most awesome person in the world." Fix a particular formalization of provability (for example, Peano Arithmetic, or Martin–Löf Type Theory). To prove that this sentence is true, suppose that it is provable. We must now show that you, dear reader, are the most awesome person in the world. If provability implies truth, then the sentence is true, and then you, dear reader, are the most awesome person in the world. Thus, if we can assume that provability implies truth, then we can prove that the sentence is true. This, in a nutshell, is Löb's theorem: to prove X, it suffices to prove that X is true whenever X is provable. Symbolically, this

$$\Box(\Box X - > X) \to \Box X$$

where $\Box X$ means "X is provable" (in our fixed formalization of provability).

Let us now return to the question we posed above: what went wrong with our original sentence? The answer is that self-reference with truth is impossible, and the clearest way I know to argue for this is via the Curry–Howard Isomorphism; in a particular technical sense, the problem is that self-reference with truth fails to terminate.

The Curry–Howard Isomorphism establishes an equivalence between types and propositions, between (well-typed, terminating, functional) programs and proofs. See Table 1 for some examples. Now we ask: what corresponds to a formalization of provability? If a proof of P is a terminating functional program which is well-typed at the type corresponding to P, and to assert that P is provable is to assert that the type corresponding to P is inhabited, then an encoding of a proof is an encoding of a program. Although mathematicians typically use Gödel codes to encode propositions and

[Copyright notice will appear here once 'preprint' option is removed.]

 $[\]overline{\ }^1$ Those unfamiliar with conditionals should note that the "if ... then ..." we use here is the logical "if", where "if false then X" is always true, and not the counterfactual "if".

Logic	Programming	Set Theory
Proposition	Type	Set of Proofs
Proof	Program	Element
Implication (\rightarrow)	Function (\rightarrow)	Function
Conjunction (\land)	Pairing (,)	Cartesian Product (\times)
Disjunction (∨)	Sum (+)	Disjoint Union (□)

Table 1. The Curry-Howard isomorphism between mathematical logic and functional programming

proofs, a more natural choice of encoding programs will be abstract syntax trees. In particular, a valid syntactic proof of a given (syntactic) proposition corresponds to a well-typed syntax tree for an inhabitant of the corresponding syntactic type.

Unless otherwise specified, we will henceforth consider only well-typed, terminating programs; when we say "program", the adjectives "well-typed" and "terminating" are implied.

Before diving into Löb's theorem in detail, we'll first visit a standard paradigm for formalizing the syntax of dependent type theory. (TODO: Move this?)

2. Quines

What is the computational equivalent of the sentence "If this sentence is provable, then X"? It will be something of the form "??? $\rightarrow X$ ". As a warm-up, let's look at a Python program that returns a string representation of this type.

To do this, we need a program that outputs its own source code. There are three genuinely distinct solutions, the first of which is degenerate, and the second of which is cheeky (or sassy?). These "cheating" solutions are:

- The empty program, which outputs nothing.
- The program print(open(__file__, 'r').read()), which
 relies on the Python interpreter to get the source code of the
 program.

Now we develop the standard solution. At a first gloss, it looks like:

```
(lambda T: '(' + T + ') -> X') "???"
```

Now we need to replace "???" with the entirety of this program code. We use Python's string escaping function (repr) and replacement syntax (("foo %s bar" % "baz") becomes "foo baz bar"):

```
(lambda T: '(' + T % repr(T) + ') \rightarrow X')
("(lambda T: '(' + T %% repr(T) + ') \rightarrow X')\n (%s)")
```

This is a slight modification on the standard way of programming a quine, a program that outputs its own source-code.

Suppose we have a function \square that takes in a string representation of a type, and returns the type of syntax trees of programs producing that type. Then our Löbian sentence would look something like (if \rightarrow were valid notation for function types in Python)

```
(lambda T: \square (T % repr(T)) \rightarrow X)
("(lambda T: \square (T %% repr(T)) \rightarrow X)\n (%s)")
```

Now, finally, we can see what goes wrong when we consider using "if this sentence is true" rather than "if this sentence is provable". Provability corresponds to syntax trees for programs; truth corresponds to execution of the program itself. Our pseudo-Python thus becomes

```
(lambda T: eval(T % repr(T)) \rightarrow X)
("(lambda T: eval(T %% repr(T)) \rightarrow X)\n (%s)")
```

This code never terminates! So, in a quite literal sense, the issue with our original sentence was that, if we tried to phrase it, we'd never finish.

Note well that the type $(\Box X \to X)$ is a type that takes syntax trees and evaluates them; it is the type of an interpreter. (TODO: maybe move this sentence?)

3. Abstract Syntax Trees for Dependent Type Theory

The idea of formalizing a type of syntax trees which only permits well-typed programs is common in the literature. (TODO: citations) For example, here is a very simple (and incomplete) formalization with Π , a unit type (\top), an empty type (\bot), and lambdas. (TODO: FIXME: What's the right level of simplicity?)

We will use some standard data type declarations, which are provided for completeness in Appendix A.

```
\begin{tabular}{ll} \hline \textbf{mutual} \\ \hline \textbf{infix} & 2 \ \_ \triangleright \_ \\ \hline \\ \hline \textbf{data} & \textbf{Context} : \textbf{Set where} \\ \hline & \varepsilon : \textbf{Context} \\ \hline & \_ \triangleright \_ : (\Gamma : \textbf{Context}) \rightarrow \textbf{Type } \Gamma \rightarrow \textbf{Context} \\ \hline \\ \hline \textbf{data} & \textbf{Type} : \textbf{Context} \rightarrow \textbf{Set where} \\ \hline & `T' : \forall \left\{\Gamma\right\} \rightarrow \textbf{Type } \Gamma \\ \hline & `L' : \forall \left\{\Gamma\right\} \rightarrow \textbf{Type } \Gamma \\ \hline & `\Pi' : \forall \left\{\Gamma\right\} \rightarrow (A : \textbf{Type } \Gamma) \rightarrow \textbf{Type } (\Gamma \triangleright A) \rightarrow \textbf{Type } \Gamma \\ \hline \\ \hline \textbf{data} & \textbf{Term} : \left\{\Gamma : \textbf{Context}\right\} \rightarrow \textbf{Type } \Gamma \rightarrow \textbf{Set where} \\ \hline & `tt' : \forall \left\{\Gamma\right\} \rightarrow \textbf{Term} \left\{\Gamma\right\} `T' \\ \hline & `\lambda' : \forall \left\{\Gamma A B\right\} \rightarrow \textbf{Term} \left\{\Gamma \triangleright A\right\} B \rightarrow \textbf{Term} (`\Pi' A B) \\ \hline \end{tabular}
```

An easy way to check consistency of a syntactic theory which is weaker than the theory of the ambient proof assistant is to define an interpretation function, also commonly known as an unquoter, or a denotation function, from the syntax into the universe of types. Here is an example of such a function:

```
 \begin{split} & \underset{\| \ \|}{\text{mutual}} \\ & \| \ \| \ \| \ \| \ : \ \text{Context} \to \text{Set} \\ & \| \ \epsilon \ \| \ c \ | \ = \ T \\ & \| \ c \ | \ c \ | \ c \ | \ T \ \| \ c \ | \ c \ | \ C \ \| \ c \ | \ C \ \| \ c \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C \ | \ C

4. This Paper

In this paper, we make extensive use of this trick for validating models. We formalize the simplest syntax that supports Löb's theorem and prove it sound relative to Agda in 13 lines of code; the understanding is that this syntax could be extended to support basically anything you might want. We then present an extended version of this solution, which supports enough operations that we can prove our syntax sound (consistent), incomplete, and nonempty. In a hundred lines of code, we prove Löb's theorem under the assumption that we are given a quine; this is basically the well-typed functional version of the program that uses open(__file__, 'r').read(). Finally, we sketch our imple-

2 2016/2/27

mentation of Löb's theorem (code in an appendix) based on the assumption only that we can add a level of quotation to our syntax tree; this is the equivalent of letting the compiler implement repr, rather than implementing it ourselves. We close with an application to the prisoner's dilemma, as well as some discussion about avenues for removing the hard-coded repr. TODO: Ensure that this ordering is accurate

5. Prior Work

TODO: Use of Löb's theorem in program logic as an induction principle? (TODO)

TODO: Brief mention of Lob's theorem in Haskell / elsewhere / ? (TODO)

6. Trivial Encoding

We begin with a language that supports almost nothing other than Löb's theorem.

```
data Type: Set where
           `\to'\quad :\mathsf{Type}\to\mathsf{Type}\to\mathsf{Type}
       \Box': Type \rightarrow Type
 data \square: Type \rightarrow Set where
      \mathsf{L\ddot{o}b}: \forall \{X\} \rightarrow \square (`\square` X `\rightarrow` X) \rightarrow \square X
\llbracket \quad \rrbracket^{\mathsf{t}} : \forall \; \{T \colon \mathsf{Type}\} \to \Box \; T \to \llbracket \; T \; \rrbracket^{\mathsf{T}}
 \llbracket \mathsf{L\"ob} \ \Box `X' \to X \rrbracket^\mathsf{t} = \llbracket \ \Box `X' \to X \rrbracket^\mathsf{t} \ (\mathsf{L\"ob} \ \Box `X' \to X)
|\ddot{\mathsf{o}}\mathsf{b}: \forall \{ X' \} \to \Box (\Box' X' \to X') \to \llbracket X' \rrbracket^\mathsf{T}
|\ddot{\mathsf{o}}\mathsf{b}\,f = [\![\mathsf{L}\ddot{\mathsf{o}}\mathsf{b}\,f]\!]^{\mathsf{t}}
```

7. Encoding with Soundness, Incompleteness, and Non-Emptyness
